HEALTH CARE ON A BUDGET

THE FINANCIAL BURDEN OF HEALTH SPENDING BY MEDICARE HOUSEHOLDS
An Updated Analysis of Health Care Spending as a Share of Total Household Spending

MARCH 2012

The Medicare program offers health and financial protection to nearly 50 million seniors and younger people with disabilities. However, the high cost of premiums, cost-sharing requirements, and gaps in the Medicare benefit package can result in beneficiaries spending a substantial share of their household budgets on health care. This brief updates our June 2011 analysis comparing the financial burden of out-of-pocket health expenses as a share of total household expenditures for Medicare and non-Medicare households, based on analysis of the 2010 Consumer Expenditure Survey. It assesses how much Medicare households are spending on health-related expenses compared to other spending priorities, the extent to which health spending as a share of household budgets varies by age and poverty level, and changes in health spending over time.

KEY FINDINGS

- Health expenses accounted for nearly 15 percent of Medicare household budgets in 2010, on average—three times the percent of health spending among non-Medicare households.
- Health insurance premiums comprised the largest share of average out-of-pocket health care spending among Medicare households in 2010—more than two-thirds of overall health spending.
- Health spending as a share of Medicare household spending increases with age, as health and long-term care needs increase and spending on other items declines.
- Medicare households with modest incomes devote a greater share of their household budgets to health care than the poorest Medicare households, primarily because Medicaid substantially reduces health care spending for low-income beneficiaries who are eligible for both Medicare and Medicaid.
- Health insurance premiums account for an increasing share of Medicare household spending over time, while the share of spending on prescription drugs has decreased.

Health expenses accounted for nearly 15 percent of Medicare household budgets in 2010, on average—three times the percent of health spending among non-Medicare households.

Spending on health care—for health insurance premiums, medical services and supplies, and prescription drugs—was a not insignificant component of household budgets at all ages in 2010, but these costs were particularly burdensome for Medicare households. On average, Medicare households devoted roughly similar shares of their budgets to food, housing, and transportation in 2010 as did non-Medicare households, but a substantially larger share to medical expenses (14.7 percent vs. 4.9 percent, respectively). The relatively high health spending burden on Medicare households is attributable to lower average household budgets overall ($30,818 vs. $49,641, respectively) and higher average health care spending among Medicare households than non-Medicare households ($4,527 vs. $2,450, respectively).

Average Household Spending = $30,818

Average Household Spending = $49,641

Health insurance premiums comprise the largest share of average out-of-pocket health care spending among Medicare households in 2010 – more than two-thirds of overall health spending.

![Components of Average Health Care Spending by Medicare Households, 2010](image)

**Spending on health insurance premiums**, including premiums for Medicare Part B, Part C (Medicare Advantage) and Part D and supplemental insurance coverage (such as Medigap and retiree health benefits), represented just over two-thirds (68.0 percent) of average health care spending by Medicare households in 2010, and 10 percent of Medicare household spending overall. Medical services (such as hospital stays, physician services, lab tests, and X-rays) comprised the next largest component of health spending by Medicare households (16.0 percent), followed by prescription drugs (13.8 percent) and medical supplies (2.3 percent).

Spending on health care excluding insurance premiums was a greater burden for Medicare households than non-Medicare households in 2010 (4.7 percent and 2.1 percent of total household spending, respectively). Non-premium health spending reflects the scope and generosity of insurance coverage for health care services, and the extent to which households use different amounts of services and incur costs as a result.

**Health spending as a share of average Medicare household spending increases with age, as health and long-term care needs increase and spending on other items declines.**

![Average Health Care Spending as a Share of Total Household Spending by Medicare Households, by Age, 2010](image)

**Spending on health care as a share of total Medicare household spending varies by age. In 2010, older households (age 80+) spent a larger share of their budgets on health care than younger households, on average. This is related to the fact that health spending tends to increase with age as health and long-term care needs rise, while spending on non-health items and overall financial resources tend to decrease. Average health care spending comprised 17.9 percent of budgets for households in which the oldest member was 80+ years old, compared to an average of 12.2 percent for the households of 65-69 year-olds, 14.2 percent for 70-74 year-olds, and 14.9 percent for 75-79 year-olds.**

Health care spending represented a smaller share of total Medicare household spending (10.7 percent, on average) for people under age 65 who qualify for Medicare due to having a permanent disability than for beneficiaries ages 65 and older. This may be related to higher rates of Medicaid coverage among younger people with disabilities on Medicare than among seniors.

---

Medicare households with modest incomes spend a greater share of their household budgets on health care than the poorest and highest-income Medicare households.

Near-poor and middle-income Medicare households (those between 100 percent and 399 percent of the poverty level) faced a greater health care spending burden in 2010 than the poorest Medicare households, those with incomes below the poverty level ($10,830/individual or $14,570/couple in 2010). For those with incomes between 100-199 percent, 200-299 percent, and 300-399 percent of the federal poverty level, average health care spending as a share of household budgets was 15.9 percent, 17.1 percent, and 14.6 percent respectively. In comparison, those with incomes below the federal poverty level spent 13.2 percent of their household budgets on health care costs, on average. Medicare households with modest incomes also had a larger spending burden than Medicare households above 400 percent of the poverty level. Yet even the highest-income group was not immune from the burden of health care costs, allocating a sizable portion of their household budgets to health care (12.7 percent).

Medicaid substantially reduces health care spending in low-income Medicare households where beneficiaries are eligible for both Medicare and Medicaid.

The smaller share of average total household spending on health care among Medicare households with incomes below 100 percent of poverty can be partly attributed to the financial protections provided by Medicaid coverage. Yet not all low-income Medicare beneficiaries are covered by Medicaid, which may be due to asset levels, a challenging eligibility and enrollment process, or lack of awareness about eligibility. This leaves many low-income households exposed to considerable health care costs. Among Medicare households with incomes below 100 percent of poverty, those with all household members also covered by Medicaid spent a considerably smaller share of household expenditures on health care in 2010 than those not covered by Medicaid (4.8 percent vs. 15.5 percent, respectively).

Absolute spending on health care in dollar amounts by Medicare households below poverty differed even more dramatically than the shares of household spending depending on whether they were covered by Medicaid. Average health care spending in 2010 by Medicare households below poverty with no members covered by Medicaid was about six times that of the health spending by Medicare households below poverty with all members covered by Medicaid ($537 vs. $3,140, respectively).
Health insurance premiums account for an increasing share of Medicare household spending over time, while the share of spending on prescription drugs has decreased.

Between 2002 and 2010, spending on health insurance premiums as a share of total Medicare household spending increased from 8.3 percent to 10.0 percent. Over these years, monthly premiums for Medicare Part B nearly doubled, from $54 per month in 2002 to $110.50 in 2010. At the same time, premiums for Medicare Advantage and Part D drug plans, and for supplemental coverage (Medigap and retiree coverage) have also been increasing, on average. Conversely, prescription drug spending as a share of average Medicare household spending decreased from 3.5 percent in 2002 to 2.0 percent in 2010. This decrease may be due in part to the introduction of the Part D drug benefit in 2006, which helps to reduce Medicare beneficiaries’ out-of-pocket drug spending.

Conclusion

Medicare households devoted nearly 15 percent of total household spending to health-related expenses in 2010, on average—a substantially larger share than non-Medicare households. Premiums for Medicare and supplemental insurance accounted for the largest share of health care spending among Medicare households, and have risen as a share of their total spending and health spending over time. Spending on prescription drugs as a share of Medicare household budgets has gradually declined.

The financial burden of out-of-pocket health care spending is felt disproportionately by some subgroups of the Medicare population, including the oldest beneficiaries and those with incomes between 100 percent and 399 percent of the federal poverty level. The lowest-income households who are dually eligible for Medicare and Medicaid face a lower health spending burden than low-income households without Medicaid, as well as Medicare households with modest incomes.

The 2010 health reform law includes provisions that could help to reduce Medicare beneficiaries’ out-of-pocket health spending over time, including closing the Part D coverage gap and eliminating cost sharing for preventive services, but the rising cost of health care overall could force many people on Medicare to make difficult choices in adjusting their household spending to account for higher costs. As policymakers consider options to reduce the federal budget deficit, including policies to rein in Medicare spending, these findings highlight the importance of assessing the effects of such proposals on out-of-pocket health care spending among Medicare beneficiaries—a majority of whom already live on tight budgets.

Methodology

This policy brief is an update of a June 2011 report of the same title. The findings are based on analysis of the Bureau of Labor Statistics Consumer Expenditure Survey Interview and Expense Files, 2002-2010. Total household spending includes food; housing; transportation; health care; entertainment; personal care products and services; reading; education; tobacco products and smoking supplies; cash contributions: life, endowment, annuities, and other personal insurance; contributions to retirement pensions and Social Security. Total health care spending includes health insurance premiums, medical services, prescription drugs, and medical supplies. Estimates were derived by summing total household expenditures and each subcomponent (e.g., housing, food, transportation, health care) across households and dividing the aggregate total amount by the aggregate amount for each subcomponent to calculate the share of total spending. The analysis focuses on average rather than median (midpoint) values to show the distribution of household spending across all components, which sums to 100 percent. All differences discussed in the text are significant at the 95 percent confidence level.
